Ringing in 2024 with fireworks, street party

The rain that fell across Singapore on the evening of Dec 31 did not deter revellers from turning up at the Marina Bay area (above left) and in the heartland such as Woodlands (right) to ring in the new year. People thronged the Marina Bay waterfront to catch the fireworks display, with the police closing access to selected areas to prevent overcrowding. MRT trains also skipped Bayfront station for around 20 minutes due to large crowds in the area. In the heartland, 5,000 residents turned up for a street party in Woodlands Ring Road, which was closed to make way for the party and a carnival. ST PHOTOS: AZMI ATHNI, SHINTARO TAY SEE LIFE • C8

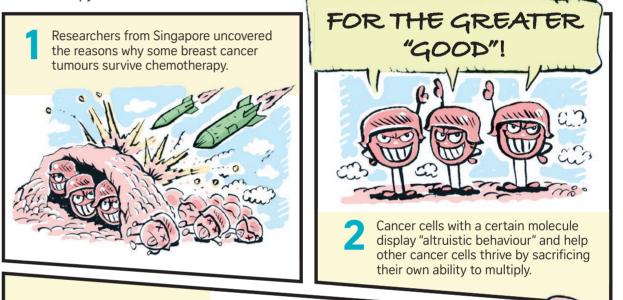

Ms Maznah Mohd Beon (third from left) was diagnosed with stage 4 breast cancer in 2018 and underwent six cycles of chemotherapy before she was told her tumour had shrunk and there was no need for a mastectomy. The cancer later returned and spread. PHOTO: COURTESY OF MAZNAH MOHD BEON

Breast cancer cells die to let surrounding ones survive: Study

The culprit behind breast cancer relapse

Contrary to the widely held belief that cancer cells seek to grow only for their own survival, a 10-year study found self-sacrificial behaviour displayed by certain breast tumour cells. They sacrifice their own growth to empower younger cancer cells to spread and resist chemotherapy.

Findings could lead to next-gen treatment targeting cancer cells' social behaviour

Correspondent

A 10-year breakthrough study discovered self-sacrificial behaviour displayed by certain breast cancer cells, causing relapse of breast cancer in some patients.

Scientists from the National University of Singapore Yong Loo Lin School of Medicine (NUS Medicine) called them "altruistic", because they sacrifice their own growth so that surrounding cancer cells can multiply and resist chemotherapy.

This unexpected discovery contradicted the widely held belief that a cancer cell seeks only its own interests for survival, and is key for more effective treatments for breast cancer.

Breast cancer is the most commonly diagnosed female cancer among Singaporean women, accounting for almost 30 per cent of all female cancers. More than 1,000 new cases are diagnosed annually and about 270 women die in Singapore each year from breast cancer. For patients with early-stage breast cancer, there is a 7 per cent to 11 per cent chance of relapse within five years of receiving initial treatment. This rate can be higher for patients in more advanced stages of the cancer. While chemotherapy aims to eliminate all cancer cells, some cancer cells may evade treatment and survive, resulting in recurrence of the cancer.

This was what happened to insurance agent Maznah Mohd Beon, 61.

She was diagnosed with stage 4 breast cancer in 2018 and went through six cycles of chemotherapy before she was told her tumour had shrunk and there was no need for a mastectomy.

"In 2020, I walked into a tree without realising it and, from then on, every time I went to the market, I started listing to my right, pushing people out of the way," she said.

"My oncologist put me through MRI (magnetic resonance imaging) and that was when she found five tumours in my brain. The canThese "altruistic" cells die to allow other cancer cells to grow and resist chemotherapy.

what is being conventionally done

by the medical community when

cer had returned and had spread." ment of Pathology at NUS Medi-Dr Leong Sai Mun from the NUS Centre for Cancer Research said The team looked at not only tu-

The team looked at not only tumour and blood samples from 63 patients with breast cancer across different stages for this study, but also laboratory-grown breast cancer cells and models.

Dr Leong said the team started 10 years ago by first analysing the blood of breast cancer patients, and it was then that they discovered a spike in a particular signal among the cancer cells from the blood.

"At that time, we were still focusing on individual cancer cells rather than the interaction. In one of these eureka moments, we mixed the cells together and found that they actually survived through chemotherapy," he said, adding that the team was not convinced and had dismissed the discovery not once, but three times.

"Eventually, we had to come to terms with the fact that there could be interactions happening between different populations of cancer cells and, in the process, the word 'altruism' popped up. (It was then that) we realised that that could be happening. We performed several experiments and different models and confirmed that it is so," Dr Leong said.

"When we mixed these populations together and treated them with chemotherapy, we expected them to overexpress themselves and survive chemotherapy," said research fellow Muhammad Sufyan Masroni from the Department of Pathology at NUS Medicine and first author of the study. "Instead, the total opposite hap-

pened. The population of treated cells actually became smaller, while the other cancer cells grew larger and became the majority of the cells."

The research paper, published in peer-reviewed journal Molecular

Cancer in December 2023, describes the complex signalling process within these "altruistic cells", which results in the tumour's overall resistance to treatment.

"Removing these altruistic cancer cells can be a potential treatment strategy. However, we may have to consider the persistence of these cells. We (also) found that the altruistic cancer cells can regenerate from the non-altruistic ones and remain within the tumour population, at a low yet consistent frequency," said Dr Sufyan. As for this discovery's implications for breast cancer treatment, Dr Leong said: "By looking at the cells socially rather than (as) individual cancer cells, we will be able to devise a new, next-generation treatment that targets their social characteristics, rather than the individualistic ones."

Associate Professor Yap Yoon Sim, a senior consultant with the Department of Breast and Gynaecological Medical Oncology at the National Cancer Centre Singapore, told The Straits Times that the study's results provide insight into the complex mechanisms cancer cells go through to avoid being killed by chemotherapy.

"These findings merit further evaluation in various settings under exposure to different drugs, before new treatment strategies can be developed to target any vulnerabilities in the network of cancer cells," she said.

Ms Maznah, who is now in palliative care, said cancer has been around for a long time, yet science has not found a cure for it.

"I hope that this is something that will materialise and although it may not be able to help me, I hope it will present itself as hope for women in the future," she said.
