

PRESS RELEASE

FOR IMMEDIATE RELEASE | 19 FEBRUARY 2024

Modifying brain molecule relaxin-3 can potentially reduce side effects in treating anxiety, depression and more

Singapore, 19 February 2024—Drugs that treat conditions like depression and anxiety often come with varying side effects, as they regulate various functions within the human body at the same time. What if these drugs could activate only the functions that target the specific conditions that they are designed to treat?

A team of researchers has found a potential way to treat these conditions with fewer side effects. Led by **Professor Gavin Dawe, Head of the Department of Pharmacology at the Yong Loo Lin School of Medicine, National University of Singapore (NUS Medicine)**, the team conducted modifications of relaxin-3—a neuropeptide, or molecule, found mainly in the human brain and nervous system—which regulates a wide range of physiological functions, including stress responses, appetite, mood and pain perception. When relaxin-3 is released in the brain, it binds to a target receptor RXFP3—to trigger a variety of signalling responses among the cells, which affect the body’s physiological processes.

However, as RXFP3 is involved in many different functions, a drug developed to treat certain conditions may cause unwanted side effects—because several of RXFP3’s signalling pathways are activated at the same time. For example, a drug that treats depression may cause adverse effects related to another function, such as feeding behaviour, which is related to eating disorders and obesity. The receptor has also been demonstrated in much existing research, including earlier work by Prof Dawe, to be a potential new target for drugs to treat these conditions. To develop better drug treatments with fewer side effects, the key is to activate only specific signalling pathways of RXFP3 that target specific conditions.

Prof Dawe’s team modified the relaxin-3 molecules, such that they activated only a part of the RXFP3 response in their interaction, instead of all the different signalling pathways. Their work, published in [Science Signaling](#), is the first discovery that modifications of relaxin-3 can lead to selective activation of some RXFP3-led signalling pathways, which is a mechanism known as biased agonism.

Prof Dawe said, “Our study has pointed to potential ways of developing drugs by modifying relaxin-3, or other neuropeptides, that can selectively activate specific functions within the body. This is important as it means drugs could be designed to have more specific effects and less undesired, adverse effects, making them more effective in managing a range of conditions like anxiety, depression, eating disorders, obesity, and addiction.”

Through a technique known as peptide stapling, the research team modified the B-chain of relaxin-3, replacing blocks of amino acids within them with artificial ones that introduce ‘chemical bridges’ between them. Alone, the B-chain is highly flexible and can twist and bend

into many different shapes, reducing its ability to be stabilised for more effective binding and activation of the receptor RXFP3. The stapling process locks the shape of the specific B-chain in relaxin-3, stabilising it for a more efficient interaction with the receptor RXFP3, where it triggers certain signalling pathways in the brain that affect the body's physiological functions.

Dr Tharindunee Jayakody, first author of the study and PhD alumna of the Department of Pharmacology at NUS Medicine, said, "We are at very early stages in terms of the journey in making clinically useful drugs. However, the promising findings from our study are a significant step in our aspiration to separately design stapled peptides that have selective effects on anxiety, depression, eating disorders and addiction. Our collaborative work would also strive to understand how proteins like RXFP3 function at a molecular level, with the help of biased agonists." She is leading a team of researchers to understand the molecular properties of proteins such as RXFP3 at the Department of Chemistry, Faculty of Science, University of Colombo, Sri Lanka, where she is a lecturer in biochemistry and molecular biology.

With the conclusion of the study, the research team plans to use different stapled peptides to understand how the signalling functions, activated by the interactions between relaxin-3 and RXFP3, affect the body's physiological functions and human behaviour.

About National University of Singapore (NUS)

The National University of Singapore (NUS) is Singapore's flagship university, which offers a global approach to education, research and entrepreneurship, with a focus on Asian perspectives and expertise. We have 16 colleges, faculties, and schools across three campuses in Singapore, with more than 40,000 students from 100 countries enriching our vibrant and diverse campus community. We have also established more than 20 NUS Overseas Colleges entrepreneurial hubs around the world.

Our multidisciplinary and real-world approach to education, research and entrepreneurship enables us to work closely with industry, governments, and academia to address crucial and complex issues relevant to Asia and the world. Researchers in our faculties, research centres of excellence, corporate labs and more than 30 university-level research institutes focus on themes that include energy; environmental and urban sustainability; treatment and prevention of diseases; active ageing; advanced materials; risk management and resilience of financial systems; Asian studies; and Smart Nation capabilities such as artificial intelligence, data science, operations research and cybersecurity.

For more information on NUS, please visit nus.edu.sg.

About the NUS Yong Loo Lin School of Medicine (NUS Medicine)

The NUS Yong Loo Lin School of Medicine is Singapore's first and largest medical school. Our enduring mission centres on nurturing highly competent, values-driven and inspired healthcare professionals to transform the practice of medicine and improve health around the world.

Through a dynamic and future-oriented five-year curriculum that is inter-disciplinary and inter-professional in nature, our students undergo a holistic learning experience that exposes them to multiple facets of healthcare and prepares them to become visionary leaders and compassionate doctors and nurses of tomorrow. Since the School's founding in 1905, more than 12,000 graduates have passed through our doors.

In our pursuit of health for all, our strategic research programmes focus on innovative, cutting-edge biomedical research with collaborators around the world to deliver high-impact solutions to benefit human lives.

The school is the oldest institution of higher learning in the National University of Singapore and a founding institutional member of the National University Health System. It is one of Asia's leading medical schools and ranks among the best in the world (Times Higher Education World University Rankings 2024 by subject and the Quacquarelli Symonds (QS) World University Rankings by subject 2023).
